Problem solving and search

Chapter 3, Sections 1–5

Outline

- ♦ Problem-solving agents
- ♦ Problem types
- \Diamond Problem formulation
- ♦ Example problems
- ♦ Basic search algorithms

Problem-solving agents

Restricted form of general agent:

```
function SIMPLE-PROBLEM-SOLVING-AGENT(p) returns an action inputs: p, a percept static: s, an action sequence, initially empty state, some description of the current world state g, a goal, initially null problem, a problem formulation state \leftarrow \text{UPDATE-STATE}(state, p) if s is empty then g \leftarrow \text{Formulate-Goal}(state) problem \leftarrow \text{Formulate-Problem}(state, g) s \leftarrow \text{Search}(problem) action \leftarrow \text{Recommendation}(s, state) s \leftarrow \text{Remainder}(s, state) return action
```

Note: this is *offline* problem solving.

Online problem solving involves acting without complete knowledge of the problem and solution.

Example: Romania

On holiday in Romania; currently in Arad. Flight leaves tomorrow from Bucharest

Formulate goal:

be in Bucharest

Formulate problem:

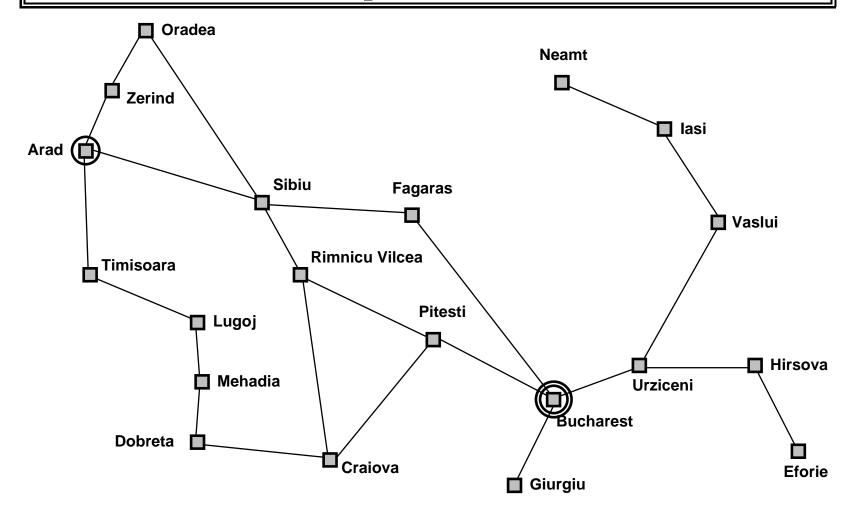

states: various cities

operators: drive between cities

Find solution:

sequence of cities, e.g., Arad, Sibiu, Fagaras, Bucharest

Example: Romania

Problem types

Deterministic, accessible $\implies single\text{-}state\ problem$ Deterministic, inaccessible $\implies multiple\text{-}state\ problem$

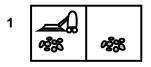

Nondeterministic, inaccessible \implies contingency problem must use sensors during execution solution is a *tree* or *policy* often *interleave* search, execution

Unknown state space $\implies exploration \ problem$ ("online")

Example: vacuum world

Single-state, start in #5. Solution??

 $\frac{\text{Multiple-state}}{\text{e.g., } Right \text{ goes to } \{2,4,6,8\}. \ \underline{\text{Solution}}??}$

Contingency, start in #5

Murphy's Law: Suck can dirty a clean carpet

య్దిష్ట

Local sensing: dirt, location only.

Solution??

Single-state problem formulation

A *problem* is defined by four items:

```
initial state e.g., "at Arad"
operators (or successor function S(x))
      e.g., Arad \rightarrow Zerind Arad \rightarrow Sibiu
                                                      etc.
goal test, can be
       explicit, e.g., x = "at Bucharest"
       implicit, e.g., NoDirt(x)
path cost (additive)
      e.g., sum of distances, number of operators executed, etc.
```

A *solution* is a sequence of operators leading from the initial state to a goal state

Selecting a state space

Real world is absurdly complex

 \Rightarrow state space must be abstracted for problem solving

(Abstract) state = set of real states

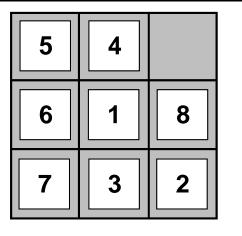

(Abstract) operator = complex combination of real actions e.g., "Arad \rightarrow Zerind" represents a complex set of possible routes, detours, rest stops, etc.

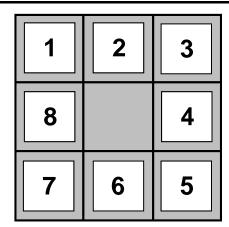

For guaranteed realizability, <u>any</u> real state "in Arad" must get to *some* real state "in Zerind"

(Abstract) solution = set of real paths that are solutions in the real world

Each abstract action should be "easier" than the original problem!

Example: The 8-puzzle

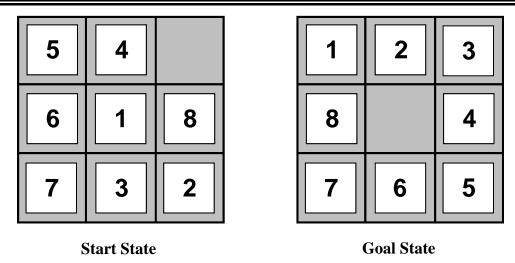

Start State

Goal State

states??
operators??
goal test??
path cost??

Example: The 8-puzzle

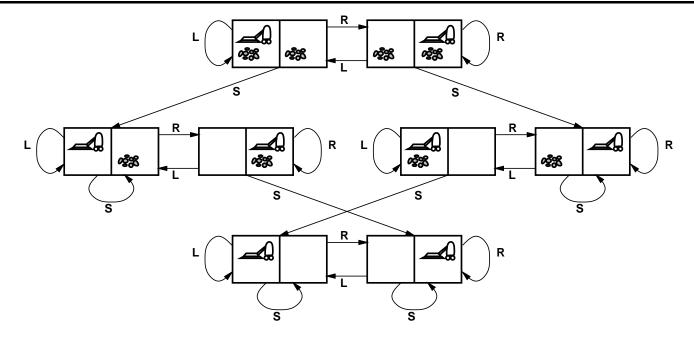

<u>states</u>??: integer locations of tiles (ignore intermediate positions)
<u>operators</u>??: move blank left, right, up, down (ignore unjamming etc.)
<u>goal test</u>??: = goal state (given)

path cost??: 1 per move

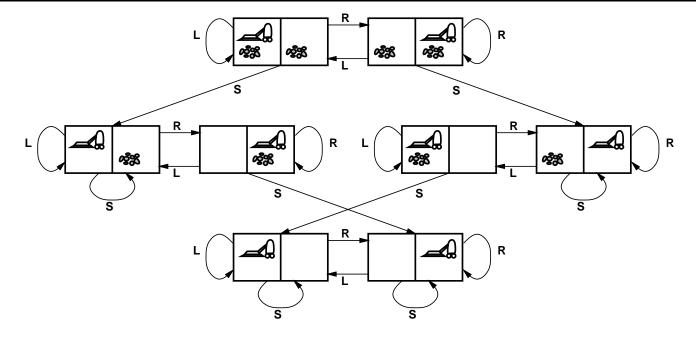

[Note: optimal solution of n-Puzzle family is NP-hard]

Example: vacuum world state space graph

states??
operators??
goal test??
path cost??

Example: vacuum world state space graph

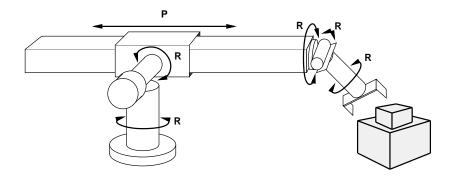

<u>states</u>??: integer dirt and robot locations (ignore dirt *amounts*)

 $\underline{\text{operators}} ??: Left, Right, Suck$

goal test??: no dirt

path cost??: 1 per operator

Example: robotic assembly

<u>states</u>??: real-valued coordinates of robot joint angles parts of the object to be assembled

operators??: continuous motions of robot joints

goal test??: complete assembly with no robot included!

path cost??: time to execute

Search algorithms

Basic idea:

offline, simulated exploration of state space by generating successors of already-explored states (a.k.a. *expanding* states)

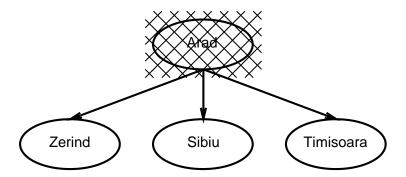

function GENERAL-SEARCH(problem, strategy) returns a solution, or failure initialize the search tree using the initial state of problem loop do

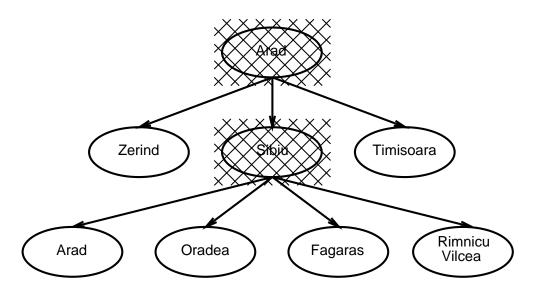

if there are no candidates for expansion then return failure choose a leaf node for expansion according to strategy

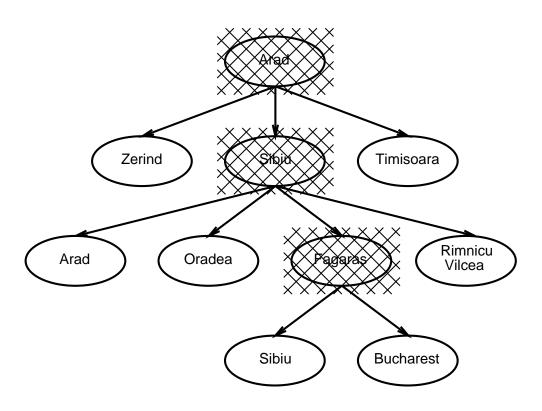

if the node contains a goal state then return the corresponding solution else expand the node and add the resulting nodes to the search tree end

General search example

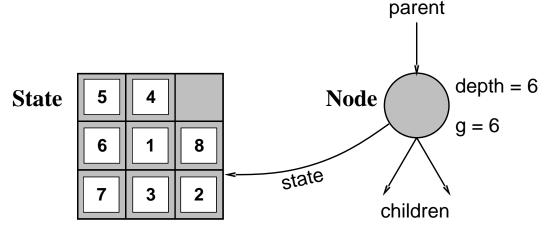

Implementation of search algorithms

```
 \begin{aligned} & \textbf{function} \text{ General-Search}(\textit{problem}, \text{Queuing-Fn}) \textbf{ returns} \text{ a solution, or failure} \\ & \textit{nodes} \leftarrow \text{Make-Queue}(\text{Make-Node}(\text{Initial-State}[\textit{problem}])) \\ & \textbf{loop do} \\ & \textbf{if } \textit{nodes} \text{ is empty } \textbf{then return} \text{ failure} \\ & \textit{node} \leftarrow \text{Remove-Front}(\textit{nodes}) \\ & \textbf{if } \text{Goal-Test}[\textit{problem}] \text{ applied to State}(\textit{node}) \text{ succeeds } \textbf{then return} \textit{ node} \\ & \textit{nodes} \leftarrow \text{Queuing-Fn}(\textit{nodes}, \text{Expand}(\textit{node}, \text{Operators}[\textit{problem}])) \\ & \textbf{end} \end{aligned}
```

Implementation contd: states vs. nodes

A state is a (representation of) a physical configuration A node is a data structure constituting part of a search tree includes parent, children, depth, path cost g(x) States do not have parents, children, depth, or path cost!

The Expand function creates new nodes, filling in the various fields and using the Operators (or SuccessorFn) of the problem to create the corresponding states.

Search strategies

A strategy is defined by picking the *order* of node expansion

Strategies are evaluated along the following dimensions:

<a href="mailto:complexes:-com

Time and space complexity are measured in terms of b—maximum branching factor of the search tree d—depth of the least-cost solution m—maximum depth of the state space (may be ∞)

Uninformed search strategies

Uninformed strategies use only the information available in the problem definition

Breadth-first search

Uniform-cost search

Depth-first search

Depth-limited search

Iterative deepening search

Breadth-first search

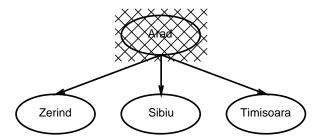

Expand shallowest unexpanded node

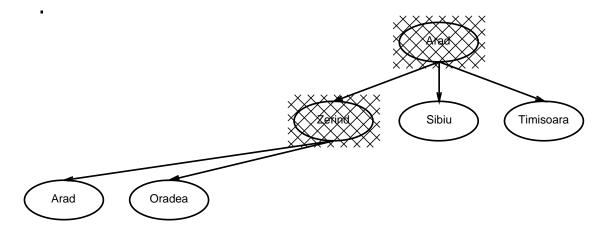

Implementation:

 $\overline{\mathrm{Q}_{\mathrm{UEUEINGFN}}} = \mathsf{put} \ \mathsf{successors} \ \mathsf{at} \ \mathsf{end} \ \mathsf{of} \ \mathsf{queue}$

•

Properties of breadth-first search

Complete??

Time??

Space??

Optimal??

Properties of breadth-first search

Complete?? Yes (if b is finite)

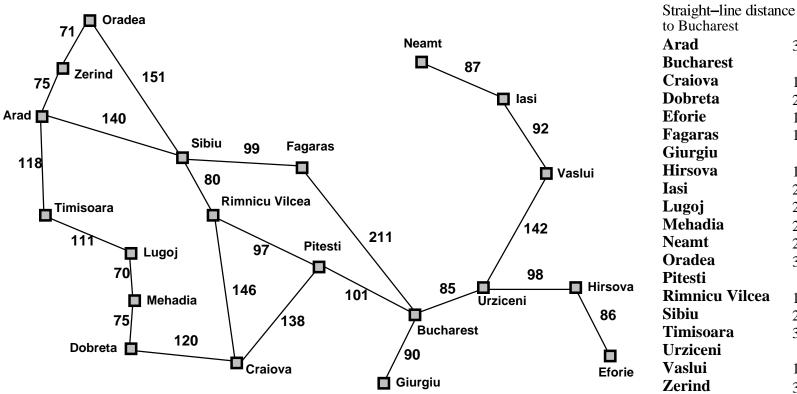

<u>Time</u>?? $1+b+b^2+b^3+\ldots+b^d=O(b^d)$, i.e., exponential in d

Space?? $O(b^d)$ (keeps every node in memory)

Optimal?? Yes (if cost = 1 per step); not optimal in general

Space is the big problem; can easily generate nodes at 1MB/sec so 24hrs = 86GB.

Romania with step costs in km

suaigni–inie distance	
o Bucharest	
Arad	366
Bucharest	0
Craiova	160
Dobreta	242
Eforie	161
Fagaras	178
Giurgiu	77
Hirsova	151
lasi	226

Uniform-cost search

Expand least-cost unexpanded node

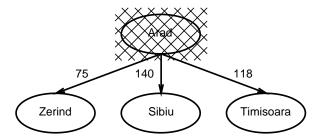

Implementation:

 $\mathrm{QueueingFn} = \text{insert}$ in order of increasing path cost

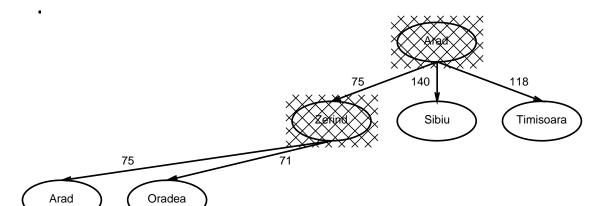

•

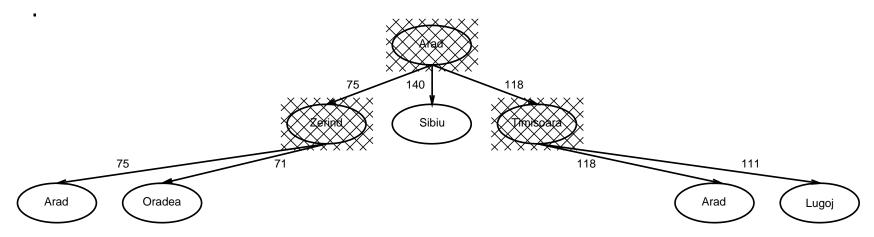

.

•

•

Properties of uniform-cost search

 $\underline{\mathsf{Complete}} ? ? \mathsf{Yes}, \mathsf{ if step cost} \geq \epsilon$

<u>Time</u>?? # of nodes with $g \leq \cos t$ of optimal solution

Space?? # of nodes with $g \leq \cos t$ of optimal solution

Optimal?? Yes

Depth-first search

Expand deepest unexpanded node

Implementation:

 $\mathrm{QueueINGFN} = \text{insert successors at front of queue}$

.

.

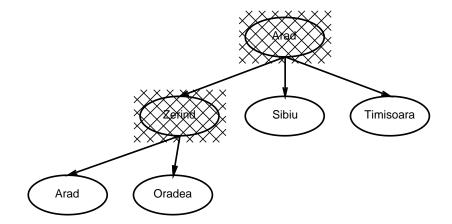

•

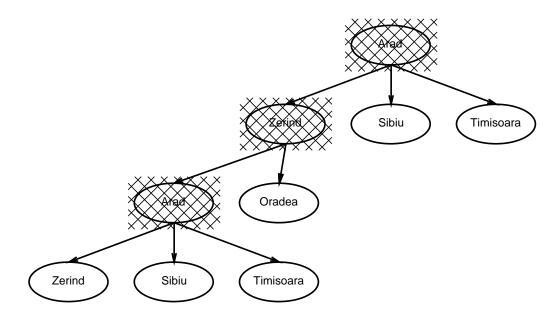

.

•

•

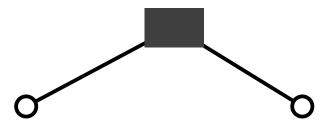

.

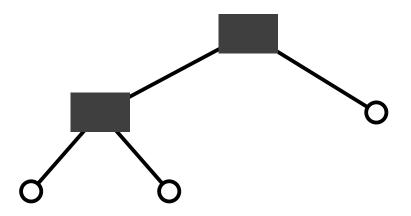

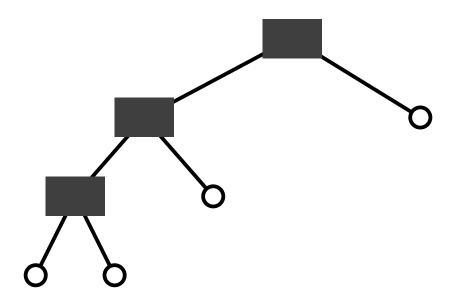

I.e., depth-first search can perform infinite cyclic excursions Need a finite, non-cyclic search space (or repeated-state checking)

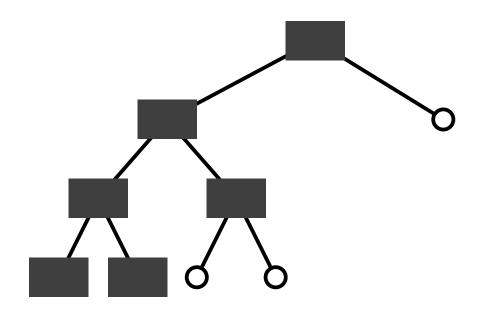

DFS on a depth-3 binary tree

O

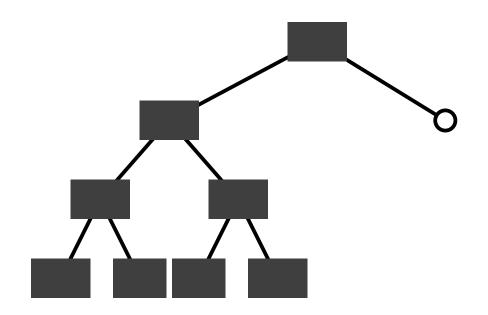

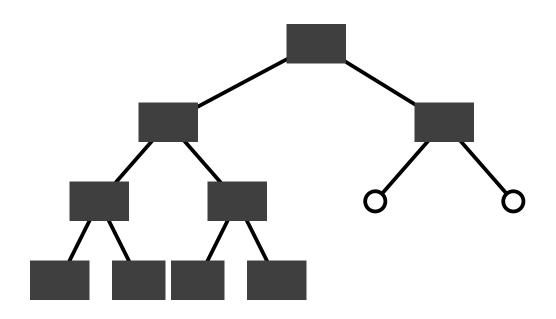

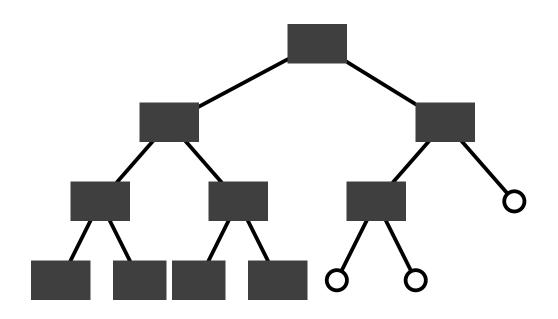

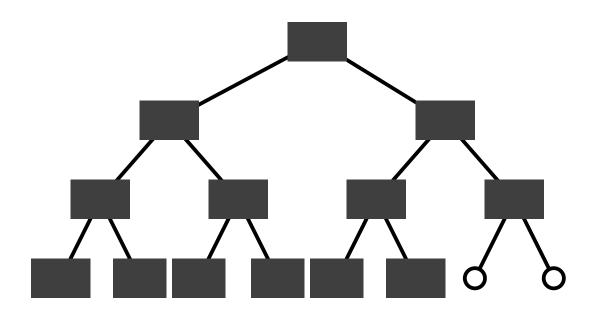

DFS on a depth-3 binary tree, contd.

Properties of depth-first search

Complete??

Time??

Space??

Optimal??

Properties of depth-first search

Complete?? No: fails in infinite-depth spaces, spaces with loops Modify to avoid repeated states along path ⇒ complete in finite spaces

<u>Time</u>?? $O(b^m)$: terrible if m is much larger than d but if solutions are dense, may be much faster than breadth-first

Space?? O(bm), i.e., linear space!

Dptimal?? No

Depth-limited search

= depth-first search with depth limit l

Implementation:

Nodes at depth l have no successors

Iterative deepening search

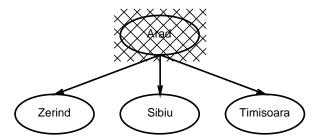

```
function Iterative-Deepening-Search(problem) returns a solution sequence inputs: problem, a problem  \begin{aligned} & \textbf{for } depth \leftarrow 0 \textbf{ to } \infty \textbf{ do} \\ & result \leftarrow \text{Depth-Limited-Search}(problem, depth) \\ & \textbf{if } result \neq \text{cutoff } \textbf{then } \textbf{return } result \\ & \textbf{end} \end{aligned}
```

Iterative deepening search l = 0

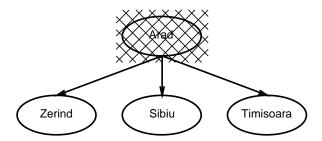

Iterative deepening search l=1

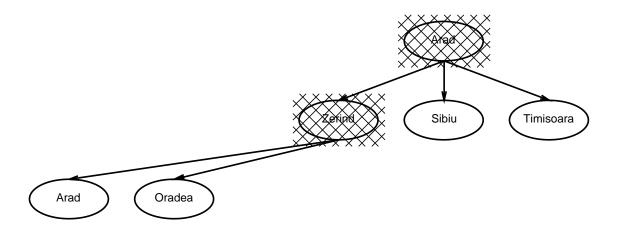

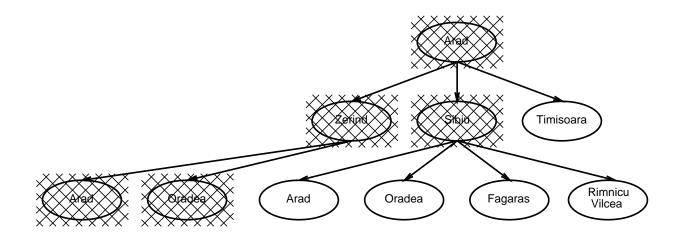

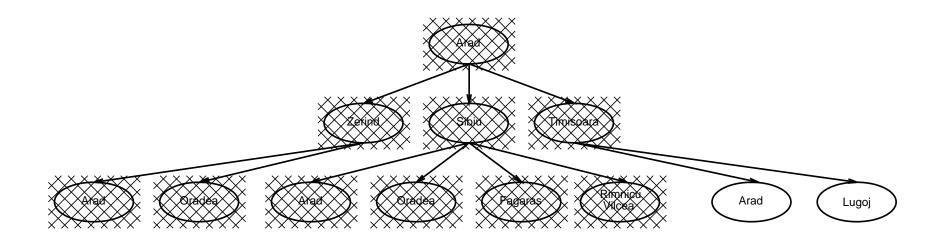

Iterative deepening search l=2

Properties of iterative deepening search

Complete??

Time??

Space??

Optimal??

Properties of iterative deepening search

Complete?? Yes

Time??
$$(d+1)b^0 + db^1 + (d-1)b^2 + \ldots + b^d = O(b^d)$$

Space?? O(bd)

Optimal?? Yes, if step cost = 1

Can be modified to explore uniform-cost tree

Summary

Problem formulation usually requires abstracting away real-world details to define a state space that can feasibly be explored

Variety of uninformed search strategies

Iterative deepening search uses only linear space and not much more time than other uninformed algorithms
